

ABSTRACT

A method for scheduling appointments. An interactive video display connected to a computer located at an Internet web site. The computer causes the display to show all or a selected portion of a selected calendar unit of time, partitioned in one dimension, into a plurality of time-slots for scheduling appointments, and partitioned in another dimension, by each of a plurality of consultants with whom the appointments are to be scheduled. A client clicks within the space associated with both one or more desired time-slots and a desired consultant to schedule an appointment with the desired consultant during the desired time. The computer responds by updating the display to show that the selected time-slot in the selected set of time-slots has been scheduled and is no longer available.
